

Bio 1M: The evolution of apes (complete)

1 Example

- Humans are an example of a biological species that has evolved
- Possibly of interest, since many of your friends are probably humans
- Humans seem unique:
 - How do they differ from other evolved organisms?
 - What do they share with other evolved organisms?

Similarities and differences

- What is different about people?
 - Answer: Complex thoughts
 - Answer: Culture
 - Answer: Language
 - Answer: Technology
- What is the same?
 - Answer: We're here because our ancestors reproduced
 - Answer: If reproductive success depends on heritable variation in traits ...
 - * Answer: We're still evolving
 - * Answer: Directional selection? Varying selection?

2 Patterns of evolution

History

- There are a *lot* of steps (and a lot of divergences) between us and the last universal common ancestor of life
- More than 3 billion years ago!
- Some key steps:
 - **Eukaryotes**
 - **Animals**
 - **Vertebrates**
 - **Mammals**
 - **Primates**
 - **Apes**

Timeline

- Why not just say how long ago?
 - Periods may be punctuated by major events
 - * * Radiations, mass extinctions
 - People started talking about periods before they had good measures of how long ago things happened
 - Periods have cool names

2.1 Context for evolution

- Adaptations build on existing adaptations – often in unexpected ways
- Evolution does not know where it's going
- In a constant environment, we would have to imagine a species just getting better and better adapted to that environment
 - and never getting stuck, e.g. vertebrate eyes
- A changing environment provides opportunities to try new combinations and build in unexpected directions

Physical changes

- Physical changes often provide species with new adaptive challenges and opportunities:
- Global climate change
- Continental drift
- Geological changes
 - New environments can arise (e.g., mountain ranges, desert basins)
 - Geology may also change connections between two populations without a large effect on how they live
 - * Rivers changing course
 - * Mountain ranges separating valley species
 - * **Answer:** Provides opportunities for allopatric speciation

Changing ecosystems

- Taxa can be dramatically affected by changes in other taxa
 - Due to evolution or to colonization
- Interactions with other organisms are key to most ecological niches
 - Who do I eat? Who is trying to eat me? How do I reproduce?
- Co-evolution is a key driver of diversity. For example:
 - Plants evolve new ways to use insects for sex, or vertebrates for dispersal
 - Animals evolve new ways to benefit from plant resources

2.2 Patterns of diversity

Therapsids

- Our ancestors radiated and dominated many terrestrial environments *before* dinosaurs did
 - I have no idea why the book refers to therapsids as reptiles; it seems very wrong:
 - * **Answer:** If they were, then we are
 - * **Answer:** One better name would be tetrapods
- Therapsids were largely replaced by dinosaurs in the age of dinosaurs
 - But some survived, and one radiated after a mass extinction

Radiation and contraction

- Many clades seem to go through periods of radiation and contraction
 - Gain and then loss of species diversity
- Examples:
 - Therapsids, apes, hominins (us)
 - **Answer:**
- Radiation gives many chances for adaptation
 - Things that have had radiations may be more likely to persist
 - Even after periods of contraction

Reasons for contraction

- Why might a clade diversify and then suffer many extinctions?
 - **Answer:** Changing conditions (climate change, continents moving)
 - **Answer:** Competition from other clades (apes vs. monkeys)
 - **Answer:** Competition from a successful member (people vs. other hominins)

Observer bias

- One reason we see a lot of clades with a history of radiations may be that those clades are the ones we're looking at
 - **Answer:** The clades that are still around
- Clades with a history of radiation may be more successful
 - They've explored more kinds of environments
 - They're found in more different specific places
 - * e.g., marsupials in Australia
 - They've had more chances to adapt
 - * May have a few very successful species (like us)

3 The evolution of primates

- **Read pp. 218-220**
- Humans are **primates**, an “order” characterized by
 - Grasping hands and feet
 - Nails and fingertips (instead of claws)
 - Highly developed **stereoscopic** vision
 - * Eyes are close together, face forward, and are used together
 - * Allows 3-d visualization
 - Hind-limb dominance
 - Large brains

Traits

- What sort of traits do biologists use to characterize a group?
 - **Answer:** Derived traits
- How would you interpret the fact that humans don't have grasping feet?
 - **Answer:** Secondary loss

The angiosperm explosion

- Flowering plants diversified very rapidly around 100 **mya** – million years ago
- This radically changed the ecology of the world, and opened up many new niches, apparently including space for primates

Primate adaptations

- There are a variety of theories for how characteristic primate adaptations evolved
- Each step was likely favored adaptively
- Likely something to do with processing and handling angiosperm fruit and flowers
 - Or else the insects that fed on these fruit and flowers

Adaptive theories

- There are many theories for why primate traits might have been adaptively favored in our ancestors
 - Leaping from branch to branch
 - Climbing and balancing on trees
 - Exploiting new plant resources
 - Catching insects
 - **Adaptive foraging**: the ability to switch between types of food, and to learn to use new types of food

Patterns of adaptation

- These strategies may have evolved sequentially
 - Maybe exploiting tree resources came first, but similar traits helped some species later catch insects
 - Maybe traits evolved for one specific purpose later became useful for adaptive foraging
 - * ***which evolved**

Sociality

- A big component of fitness may be based on co-operating with (or at least being tolerated by) **conspecifics** – other members of your species
- Brains that evolved for complicated foraging may have also been useful for social skills
- Looping: once sociality was present, adaptation for social thinking and thinking about food may have interacted to increase selection for brain size

3.1 Tools for learning about the past

Getting fed

- A major factor in adaptation is food source.
- The most important strategies for early primates were:
 - **Frugivory**: eating fruits (and sometimes flowers)
 - **Folivory**: eating leaves
 - **Insectivory**: eating insects

Teeth

- Teeth are very important for processing food
- Why do we have wisdom teeth?
 - **Answer**: An adaptation to make it more likely we will have functional teeth in middle age
 - **Answer**: This is probably also why we have two sets of teeth
- Teeth help scientists understand what extinct animals ate
 - Well preserved, highly adapted

Eyes

- Eye **orbits** are the skeletal cavities where eyes are
- Orbits tell us size, shape and position of eyes from fossil animals
- What are the advantages and disadvantages of more forward-facing eyes?
 - **Answer**: Better for precise tasks, three-dimensional visualization
 - **Answer**: Not as good for looking around, being alert
- What are the advantages and disadvantages of larger eyes?
 - **Answer**: Better for night vision
 - **Answer**: More costly? Better for day vision?

Sexual dimorphism

- Information about differences between males and females has implications about social structure and mating patterns
 - In species where there is more variation in male success (less bonding in pairs), we expect:
 - * **Answer**: More sexual dimorphism
 - * **Answer**: More competition between males for females

Dimorphism and sexual strategies

- Gorillas live in male-centered groups (one adult male, several adult females)
- Chimpanzees live in large, well-mixed groups with lots of interactions between males and females
- Which species should have more sexual dimorphism overall?
 - **Answer:** Gorillas. Males are huge and strong and compete for females by displaying and fighting. A dominant male has exclusive access to a group of females
- Which species should have larger male genitals?
 - **Answer:** Chimpanzees have much larger genitals.
 - **Answer:** Gorillas don't use genitals as part of sexual competition
- What about humans?
 - *Comment:* I am not writing this one down

3.2 Challenges in learning about the past

Interpreting fossil traits

- There is lots of ongoing debate about relationships between extinct primates
- We know a lot about omomyids and adapids
- How do we not know how they relate to modern primates?
 - **Answer:** Convergent evolution

What was where when?

- When are two specimens from the same species?
- How do we learn clues to tell *sexes* apart, and recognize which dimorphic individuals are from the same species?
- How do we know what fossils we *didn't* find?

4 The evolution of apes

Anthropoids

- **Anthropoids** is the sub-group of primates including apes and monkeys
 - **Answer:** Monkeys are not a clade!

Ape adaptations

- Apes are more adapted for swinging through trees, whereas monkeys are more adapted for climbing and leaping
- More upright
- Better at hanging, and worse at sitting
- Lots of missing pieces of the puzzle
 - There may be a lot of convergent evolution and secondary loss going on

Patterns of replacement

- Apes “radiated” into many habitats before monkeys did
 - Many ape species were apparently later replaced by monkeys
- Why might apes have diversified, and later been replaced by monkeys?
 - Answer: Changing climactic conditions
 - Answer: Changes in plants or insects
 - Answer: Unpredictable adaptive innovations
- What if the ape radiation had never happened?
 - Answer: Probably no people

Summary

- People have important differences from other organisms
- We got here using the same rules of natural selection as everyone else
 - Things may be different *now*, but even that is not so clear
- Adaptation does not move in a straight line
 - Changing conditions lead to opportunities for new adaptations
 - New adaptations *themselves* can be an important cause of changing conditions
 - * Innovations, or co-evolution with other taxa

Learning about evolution

- Understanding the course of evolution is an important part of understanding how things work now
 - How organisms work, and how ecosystems work
- There are many challenges:
 - Timelines, identification, convergent evolution
